TITLE : NONAQUEOUS ELECTROLYTE  
SECONDARY BATTERY

ABSTRACT : PROBLEM TO BE SOLVED: To provide a nonaqueous electrolyte secondary battery without deterioration of battery characteristics such as the deterioration of a current collecting characteristic, due to floating of the positive electrode active material and the rise in impedance due to a nonconductive layer to be formed in an interface between a metal collector and the positive electrode active material due to the corrosion of the metal collector.

SOLUTION: In a nonaqueous electrolyte secondary battery, having a positive plate formed with a positive electrode active material layer, mainly composed of the lithium contained compound oxide in a surface of a collector formed of an aluminum foil to be corroded by the strong alkali, a coating property of the positive electrode active material paste and a current-collecting characteristic of the aluminum foil are improved by reducing the corrosion of the aluminum foil, while adding MoO<sub>3</sub> at 10-10,000 ppm of weight ratio with respect to the positive electrode active material to the viscous aqueous solution composed of the positive electrode active material, a thickener, conductive agent and binder.
